**The Sustainable  
Water Resource  
Engineering Laboratory  
at Drexel University**

# Urban hydrology

# Objectives

- Quantify canopy interception by different shrub species
- Investigate difference in interception performance between a small isolated and a closed canopy
- Investigate hydrological significance of interception by a shrub canopy

IMPACT ON RUNOFF GENERATION

15

15

# Discussion

- LAI is not a dominant canopy traits influencing interception performance
- Isolated canopies demonstrate different than continuous canopies rates of water removal
- Can we effectively implement hydrological benefits of interception by small canopies?

DREXEL UNIVERSITY

Civil, Architectural, and  
Environmental Engineering  
*College of Engineering*

# Future work

- Stemflow
- Identify, if any, TF lateral displacement

- Create (multiple?) regression model
- Inform H&H models

DREXEL UNIVERSITY

Civil, Architectural, and  
Environmental Engineering

College of Engineering

RESULTS

20

# Preliminary conclusions

- Horizontally projected canopy area receives 13- 50% less water than adjacent reference sites
- Interception fractions vary by species
- Canopy properties seem to play a key role
- Drop-splash evaporation is suspected
